2.2.9. Capillary viscometer method

The determination of viscosity using a suitable capillary viscometer is carried out at a temperature of 20 ± 0.1 °C, unless otherwise prescribed. The time required for the level of the liquid to drop from one mark to the other is measured with a stop-watch to the nearest one-fifth of a second. The result is valid only if two consecutive readings do not differ by more than 1 per cent. The average of not fewer than three readings gives the flow time of the liquid to be examined.

Calculate the dynamic viscosity \( \eta \) (2.2.8) in milliPascal seconds using the formula:

\[
\eta = \frac{k \rho t}{d}
\]

where:
- \( k \) = constant of the viscometer, expressed in square millimetres per second squared,
- \( \rho \) = density of the liquid to be examined expressed in milligrams per cubic millimetre, obtained by multiplying its relative density \( d \) by 0.9982,
- \( t \) = flow time, in seconds, of the liquid to be examined.

The constant \( k \) is determined using a suitable viscometer calibration liquid.

To calculate the kinematic viscosity \( v \) (2.2.5), use the following formula:

\[
v = k t
\]

(1) The European Pharmacopoeia describes the system proposed by the International Organisation for Standardization (ISO).
The determination may be carried out with an apparatus (Figure 2.2.9.-1) having the specifications described in Table 2.2.9.-1:

Figure 2.2.9.-1. – Suspended level viscometer
Dimensions in millimetres
The minimum flow time should be 350 s for size no. 1 and 200 s for all other sizes.
Method. Fill the viscometer through tube ($L$) with a sufficient quantity of the liquid to be examined, previously brought to 20 °C unless otherwise prescribed, to fill bulb ($A$) but ensuring that the level of liquid in bulb ($B$) is below the exit to ventilation tube ($M$). Immerse the viscometer in the bath of water at 20 ± 0.1 °C, unless otherwise prescribed, maintain it in the upright position and allow to stand for not less than 30 min to allow the temperature to reach equilibrium. Close tube ($M$) and raise the level of the liquid in tube ($N$) up to a level about 8 mm above mark ($E$). Keep the liquid at this level by closing tube ($A$) and opening tube ($M$). Open tube ($A$) and measure, with a stop-watch to the nearest one-fifth of a second, the time required for the level of the liquid to drop from mark ($E$) to ($F$).

2.2.10. VISCOSITY - ROTATING VISCOMETER METHOD
The principle of the method is to measure the force acting on a rotor (torque) when it rotates at a constant angular velocity (rotational speed) in a liquid. Rotating viscometers are used for measuring the viscosity of Newtonian (shear-independent viscosity) or non-Newtonian liquids (shear dependent viscosity or apparent viscosity). Rotating viscometers can be divided into 2 groups, namely absolute and relative viscometers. In absolute viscometers the flow in the measuring geometry is well defined. The measurements result in absolute viscosity values, which can be compared with any other absolute values. In relative viscometers the flow in the measuring geometry is not defined. The measurements result in relative viscosity values, which cannot be compared with absolute values or other relative values if not determined by the same relative viscometer method.

Different measuring systems are available for given viscosity ranges as well as several rotational speeds.

APPARATUS
The following types of instruments are most common.

CONCENTRIC CYLINDER VISCOMETERS (ABSOLUTE VISCOMETERS)
In the concentric cylinder viscometer (coaxial double cylinder viscometer or simply coaxial cylinder viscometer), the viscosity is determined by placing the liquid in the gap between the inner cylinder and the outer cylinder. Viscosity measurement can be performed by rotating the inner cylinder (Searle type viscometer) or the outer cylinder (Couette type viscometer), as shown in Figures 2.2.10.-1 and 2.2.10.-2, respectively. For laminar flow, the viscosity (or apparent viscosity) $\eta$ expressed in pascal-seconds is given by the following formula:

$$\eta = \frac{1}{\omega} \left( \frac{M}{4\pi h} \right) \left( \frac{1}{R_i^2} - \frac{1}{R_o^2} \right) = k \frac{M}{\omega}$$

$M$ = torque in newton-metres acting on the cylinder surface,
$\omega$ = angular velocity in radians per second,
$h$ = height of immersion in radians per second,
$R_i$ = radius in metres of the inner cylinder in the liquid medium,
$R_o$ = radius in metres of the outer cylinder,
$k$ = constant of the apparatus, expressed in radians per cubic metre.
